COMPUTER ENGINEERING DEPARTMENT

Academic Year:2016-17

PUNE INSTITUTE OF COMPUTER TECHNOLOGY,
DHANKAWADI PUNE-43.

CERTIFICATE

ISO 9001 : 2008 Certified

*This is to certify that Miss. Jagruti Rajendra Waghulde
Roll.No. 3323 a student of T.E. (Computer Engineering
Department) Batch 2016-2017, has satisfactorily completed a
seminar report on
“Security in Software Defined Networks using Firewall”
under the guidance of prof. Sumit Shinde towards the partial
fulfillment of the third year Computer Engineering Semester II
of Pune University.*

Place:- PICT, Pune.

SECURITY IN SOFTWARE DEFINED NETWORKS USING FIREWALL.

ABSTRACT:

Software Defined Network architecture decouples the network control and forwarding functions enabling the network control to become directly programmable and the underlying infrastructure to be abstracted for applications and network services.

Following includes the demonstration of a layer 2 firewall using a tree topology with POX Controller, a switch and three hosts. Implementation includes POX controller at control plane of the architecture using Mininet. The implemented code successfully controls flow of packets between hosts according to firewall rules.

Implementation also includes a zone-based firewall designed and Simulated in GNS3 using three routers, switches and underlaying hosts.

KEYWORDS:

Software Defined Networking, SDN Security, SDN based firewall, POX, Mininet, Zone based Firewall.

INTRODUCTION:

SDN separates the control plane of networking device (switch/ router) from its data plane, making it possible to control, monitor, and manage a network from a centralized controller.

Network Security is an important issue of today's Networking. Recently, Software Defined Networking is an evolving technology that decouples the control from forwarding network devices like switches, routers, hubs etc. SDN splits data plane and control plane . It controls the flow of data through high level program. Since in SDN network control is done programmatically network security is more vital task .

Firewalls are essential components in a network that act as a first level of access control. It protects the local network from other hosts in Internet, which are not trustworthy. Packet filtering can be done at the different levels of the network layer.

A centralized SDN firewall, which centrally defines and enforces the firewall policy on top of a controller, can immediately enforce updated rules in the firewall policy to check security violations.

For increasing the security of SDN firewalls zone based firewalls can be used. Zone based Firewalls are used for stateful inspection of the traffic. Ordinary firewall rule sets are applied on a per-interface basis to act as a packet filter for the interface. In a zone-based firewall, interfaces are grouped into security "zones," where each interface in a zone has the same security level.

1) MOTIVATIONAL SURVEY:

The programmability and centralized control of the network topology in SDN allow enterprises to incorporate various applications easily to improve efficiency, reduce complexity, streamline processes, and provide superior user experience.

The need of securing the network from malicious attacks as well as from viruses and worms lead to the introduction of firewalls in software defined networks

2) LITERATURE REVIEW:

One of the fundamental challenges of SDN is to build robust firewalls for protecting OpenFlow-based networks where network states and traffic are frequently changed.

An example of SDN firewall application has been introduced in pox controller where each packet-in behavior triggered by the first packet of a traffic flow which is matched against a set of existing firewall rules that allow or deny a flow at its ingress switch. This preliminary implementation of OpenFlow-based firewall application can examine flow packet violations when new flows come in the network but it cannot check flow policy violations with respect to dynamic network policy updates.

To build robust firewall, Alaauddin Shieha introduce FLOWGUARD , is a comprehensive framework, to facilitate accurate detection as well as effective resolution of firewall policy violations in dynamic OpenFlow-based networks. when network states are updated, FLOWGUARD checks network flow path spaces to detect firewall policy violations. In addition, with the help of several innovative resolution strategies designed ,it conducts automatic and real-time violation resolutions for diverse network update situations. ALAAUDDIN SHIEHA also implement his framework and demonstrate the efficiency of the proposed detection and resolution approaches in FLOWGUARD through experiments with the help of a real-world network topology.

Extract from an IEEE paper:

Building Firewall over the Software-Defined Network Controller : Written by Michelle Suh, Sae Hyong Park, Byungjoon Lee, Sunhee Yang.

There were two approaches considered in implementing the firewall: a) pre-installing the rules onto the switch's flow table and b) handling the packets directly as they come in. We chose to handle the incoming packets directly because of the flexibility in management.

The logic of the firewall is as follows:

Each packet headers are checked against the firewall rule from highest to lowest priority, and performs specified action once matching fields are found in the rule. Any unmatched packets are dropped. Installing firewall rules are possible from an external entity through a text-based user interface.

3) APPLICATIONS:

- In networks where internal traffic needs to be filtered or inspected
- In networks where centralized control is very important.
- Packets are monitored and filtered at a central location thus useful in organizations where security plays a very important role.

4) CHALLENGES IN DOMAIN:

- Complex Configurations.
- Less number of user friendly interfaces available.
- Tough to maintain persistence.
- Needs to learn multiple tools.

MATHEMATICAL MODEL:

Let S be the System where,

$S = \{s, c, sw, ho, h1, h2, e\}$

Where,

s = start state

c = POX controller

$c = \{f, I, h, l\}$

where, f = Fetch or load MAC addresses to be blocked by the firewall from .csv file.

$f \in \{\text{input file with id, source MAC address, destination MAC address}\}$

I = Initiate Openflow protocol with the topology.

h = Handle up connections.

Where, $h = \{m, fmod, actions, log\}$

m = Match function

where, $m = \{\text{source, destination}\}$

where, source = {Source MAC Address}

destination = {Destination MAC Address}

fmod = construct flow modify message

actions = Perform appropriate actions according to the rules.

log = logs written

l = launch function.

Where, $l = \{\text{Register and launch the firewall}\}$

sw = Switch

$sw \in \{\text{Tree Topology}\}$

h0 = host 1

$h0 \in \{\text{Tree Topology}\}$

h1 = host 2

$h1 \in \{\text{Tree Topology}\}$

h2 = host 3

$h2 \in \{\text{Tree Topology}\}$

e = end state.

DESIGN AND ANALYSIS OF THE SYSTEM:

- **SDN Firewall:**

Since a software defined network decouples the data forwarding and control plane. Security must be enforced so as to make our system resistant of malicious attacks. Implementing a Firewall on the software Defined Network which can inspect, monitor, filter the traffic passing through it. Internal traffic is not seen and cannot be filtered by a traditional firewall. An SDN based firewall works both as a packet filter and a policy checker. The first packet goes through the controller and is filtered by the SDN firewall. The subsequent packets of the flow directly match the flow policy defined in the controller. The firewall policy is centrally defined and enforced at the controller.

Fig: Software Defined Network Firewall

A Comparison between Traditional and SDN Firewall:

Parameters	Traditional Network Firewall	SDN Firewall
1. Stateful inspection	Track the state of traffic present on layers 2 to 4.	Track the state of layer 2 to 7.
2. Integrated IPS and IDS	The IPS or IDS deployment is done with the help of a separate appliance or an appliance that is logically separated with the single appliance.	Intrusion Detection System (IDS) and Intrusion Protection System (IPS) is fully integrated.
3. Identity Awareness	Not supported.	Keeps the track of the identity of local traffic device and user.

IMPLEMENTING A SDN BASED FIREWALL:

The system analyses data packets for parameters like L2/L3 headers (i.e., MAC and IP address) or performs deep packet inspection (DPI) for higher layer parameters (like application type and services etc) to filter network traffic.

I have implemented a layer 2 firewall that runs alongside the MAC learning module on the POX OpenFlow controller. The firewall application is provided with a list of MAC address pairs i.e., access control list (ACLs). When a connection establishes between the controller and the switch, the application installs flow rule entries in the OpenFlow table to disable all communication between each MAC pair.

It consists of two files:

firewall.py: Contains logic for installing firewall rules. It consists of a firewall class that has a `_handle_ConnectionUp` function. It also has a global variable, `policyFile`, that holds the path of the firewall-policies.csv file. Whenever a connection is established between the POX controller and the OpenFlow switch the `_handle_ConnectionUp` functions gets executed.

firewall-policies.csv: A list of MAC pairs (i.e., policies) read as input by the firewall application.

```
id,mac_0,mac_1
1,00:00:00:00:00:01,00:00:00:00:00:02
firewall.csv file contains rules as above
```

Program reads the policy file and update the `_handle_ConnectionUp` function. The function should install rules in the OpenFlow switch that drop packets whenever a matching src/dst MAC address (for any of the listed MAC pairs) enters the switch. This will cause the firewall application to install a flow rule entry to disable all communication between host (h1) and host (h2).

ZONE BASED FIREWALL:

Fig: A Zone Based Firewall

Ordinary firewall rules sets are applied on a per-interface basis to act as a packet filter for the interface. In a zone-based firewall, interfaces are grouped into security “zones,” where each interface in a zone has the same security level.

Packet-filtering policies are applied to traffic flowing between zones. Traffic flowing between interfaces that lie in the same zone is not filtered and flows freely because the interfaces share the same security level.

STEPS IN SETTING UP A ZONE BASED FIREWALL:

Step 1 - Define the Zone Names and create zones

Zone security R1

Step 2 – Put the correct interface in zone

Zone-member security R1

Step 3- Define the Zone Pairs (direction of traffic flow)

Zone-pair security LAN2INTERNET source R1 destination R3

Step 3 - Create a Policy Maps and class for Zone Pairs

Class class-default

Step 4- Assign the Policy Map to a Zone Pair

Policy-map type inspect LAN2INTERNET

Step 5-Specify the matching protocols.

Match protocol ICMP

Step 6 – Verification (ping)

Rules of Zone-Based Firewall:

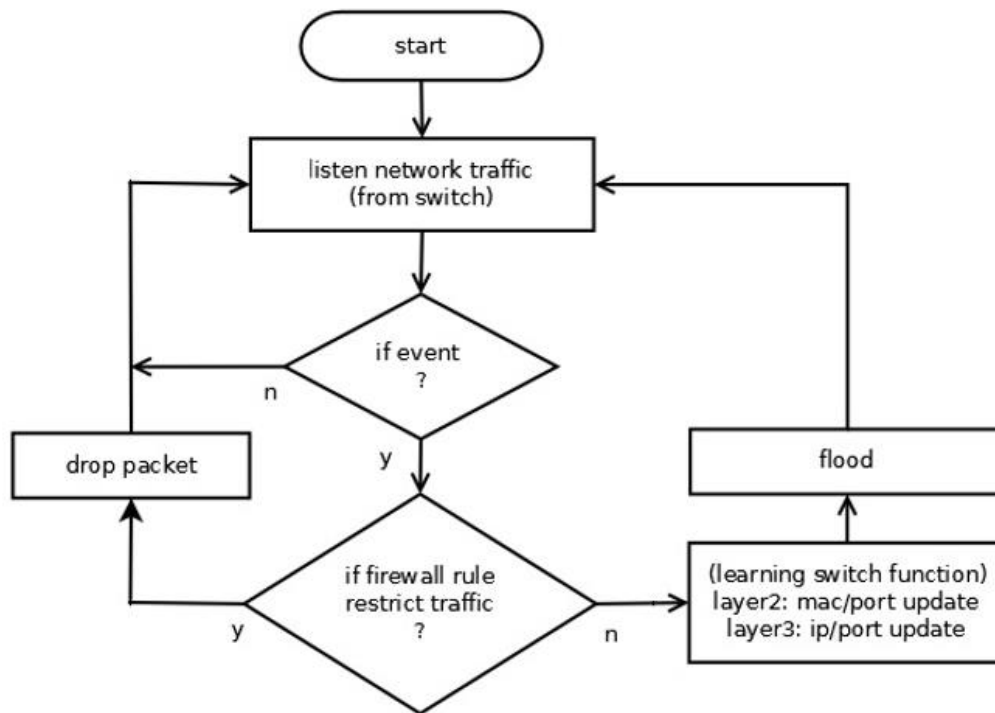

A zone must be configured before interfaces can be assigned to the zone.

An interface can be assigned to only one security zone. All traffic to and from a given interface is implicitly blocked when the interface is assigned to a zone, except traffic to and from other interfaces in the same zone, and traffic to any interface on the router.

Traffic is implicitly allowed to flow by default among interfaces that are members of the same zone. In order to permit traffic to and from a zone member interface, a policy allowing or inspecting traffic must be configured between that zone and any other zone.

DISCUSSION OF IMPLEMENTATION OF RESULTS:

- Flow chart for firewall implementation:

SNAPSHOTS FROM THE SDN FIREWALL IMPLEMENTATION:

```
mininet@mininet-vm: ~
mininet@192.168.56.101's password:
Welcome to Ubuntu 14.04.4 LTS (GNU/Linux 3.13.0-85-generic i686)

 * Documentation:  https://help.ubuntu.com/

Last login: Sun Mar 26 19:22:01 2017 from 192.168.56.1
mininet@mininet-vm:~$ sudo mn --topo single,3 --controller remote --mac
*** Creating network
*** Adding controller
Unable to contact the remote controller at 127.0.0.1:6633
*** Adding hosts:
h1 h2 h3
*** Adding switches:
s1
*** Adding links:
(h1, s1) (h2, s1) (h3, s1)
*** Configuring hosts
h1 h2 h3
*** Starting controller
c0
*** Starting 1 switches
s1
*** Starting CLI:
mininet>
```

The screenshot shows a terminal window titled 'mininet@mininet-vm: ~'. It displays the output of the 'mn' command, which sets up a Mininet topology. The output includes the creation of a network, adding a controller (c0), adding hosts (h1, h2, h3), adding a switch (s1), and adding links between them. The CLI is then started, and the prompt 'mininet>' is shown.

Starting the mininet topology.

Starting the POX Controller:

```
mininet@mininet-vm: ~/pox
firewall.py      gephi_topo.py      mac_blocker.py      telnetd

CONCLUSION AND FUTURE ENHANCEMENT:

- SDN firewalls are more secure as compared to the traditional and they are more flexible & programmable. Software defined network firewalls results in securing the network by filtering the ingress as well as egress traffic using ACL (access control list). Clubbing Zone based firewalls and SDN Firewalls will make SDN firewalls even more secure, Since the network will be grouped into zones increasing security thereby making it easy to enforce rules/policies on firewalls.
- When software controls network functions, you can manage and change network functions quickly and easily. The software makes it easy to set up and manage. This will help simplify on-site network infrastructure upgrades and deployments and streamline operations, meaning that you can deploy network functions such as a new router or firewall without waiting and without installing additional on-site hardware.
- **Space and cost savings:** With a network based on software rather than physical equipment, customers invest less in hardware and need less space in the server room.
- **Enhanced security:** SDN enhances security because it is easier for the network service provider to respond to and deploy updates when there is an attack. It is also possible to isolate and contain problems more easily. In the case of a Distributed Denial of Service (DDoS) attack, we can scale the network in near real time to avoid major disruption to customer networks.
- SDN openflow plays a major role in centralizing control while helps SDN firewalls to be deployed at controller useful in avoiding worms and viruses in internal network. Hence it is highly adopted by organizations.
- Demilitarized zone can be used with the sdn firewall to increase security.
- Security enhancement can be done by implementing the firewalls at different layers of network dealing with layer respective protocols such as:
 - i) TCP/UDP :- Layer 4
 - ii) IP :- Layer 3
 - iii) MAC addresses :- Layer 2
- The future of SDN is nothing short of bright. In fact, we expect SDN to become broadly pervasive over the next five years, as standards progress, the benefits become quantified, and end-user organizations proceed down the experience curve.
- One of the very interesting possibilities now appearing is the merging of SDN with that other leading-edge trend in networking, *network function virtualization (NFV)*. NFV, like all virtualization technologies, substitutes software-based constructs for what would otherwise require dedicated hardware.
